

Pseudocode for Loading Data into Vector Data Structure:

1. Open the document containing information about the courses.
2. Check if the document opened successfully.
3. Initialize an empty vector data structure to store course objects.
4. While not reaching the end of the document:
 - 4.1. Read a line from the document.
 - 4.2. Parse the line to extract course number, title, and prerequisites.
 - 4.3. Check if the line contains at least two parameters.
 - 4.4. If not, log an error and move to the next line.
 - 4.5. If there are prerequisites:
 - 4.5.1. Check if each prerequisite exists as a course in the document.
 - 4.5.2. If any prerequisite does not exist, log an error, and move to the next line.
 - 4.6. Create a new course object.
 - 4.7. Store course number, title, and prerequisites (if any) in the course object.
 - 4.8. Add the course object to the vector data structure.
5. Close the document.

Pseudocode for Searching and Printing Course Information:

1. Initialize a variable to store the target course number.

2. Ask the user to enter the course number they want to find.
3. Read the input course number.
4. Iterate through the vector data structure:
 - 4.1. If the course number matches the target course number:
 - 4.1.1. Print course information: number, title, and prerequisites.
 - 4.1.2. If there are prerequisites:
 - 4.1.2.1. Iterate through the prerequisites:
 - 4.1.2.1.1. Print each prerequisite.
 - 4.1.3. Exit the loop.
5. If no matching course is found, print an error message.
